

Estimation of non-additive variance components and SNP effects in five dairy cattle breeds

Andrew Marete

The Premise

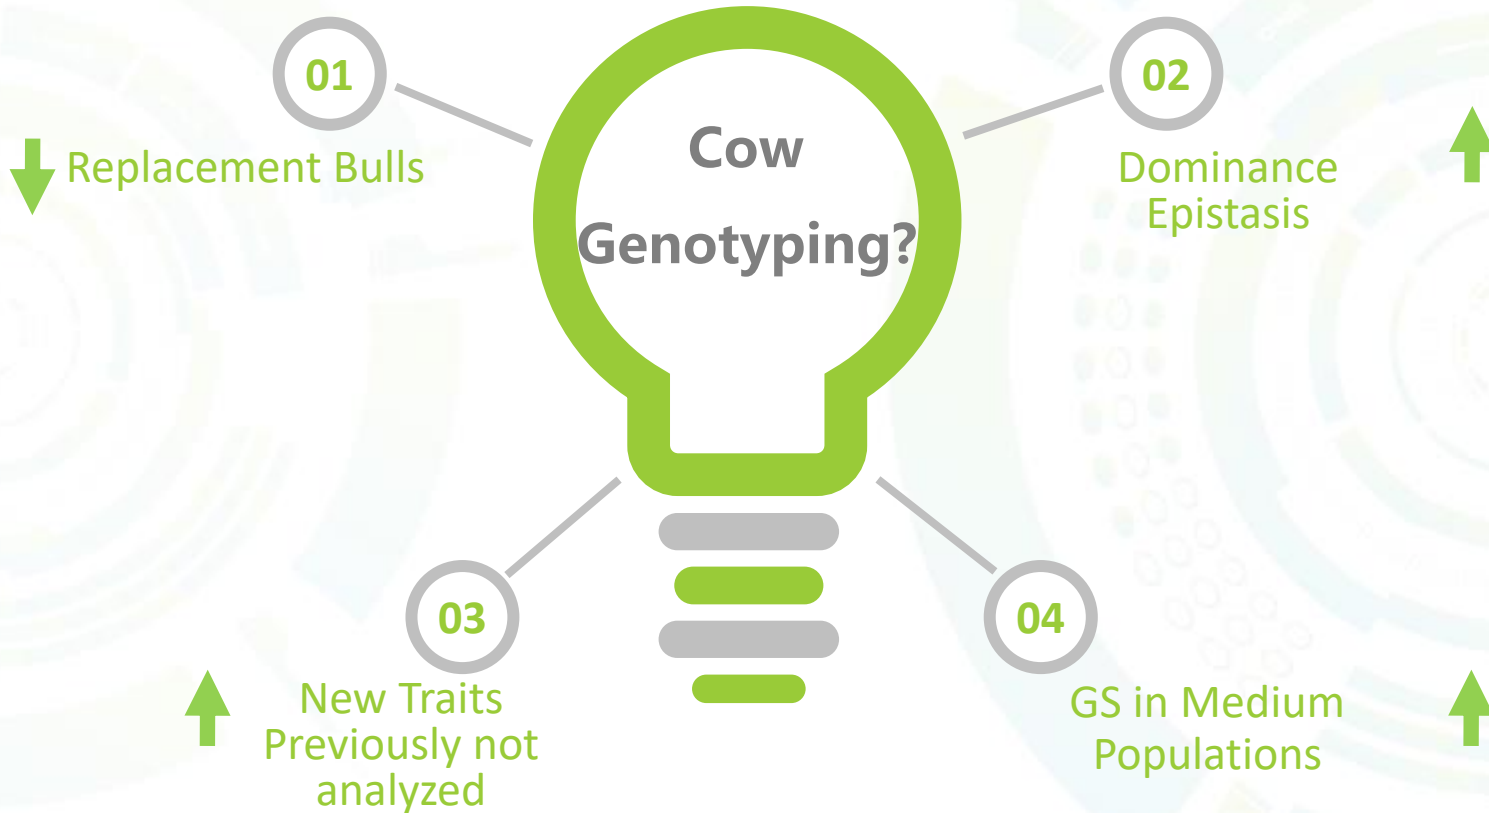

- Milk production traits are affected by many genes, many with a small effect and some with a major effect, thus complex traits
- Complex traits are regulated by complex interplay between multiple genes
- Theoretically, these genes can interact
- Interaction can be explained as non-additive genetic variance (NAGV)
 1. same locus interaction (dominance deviation)
 2. different loci interaction (epistatic variance)

The challenge

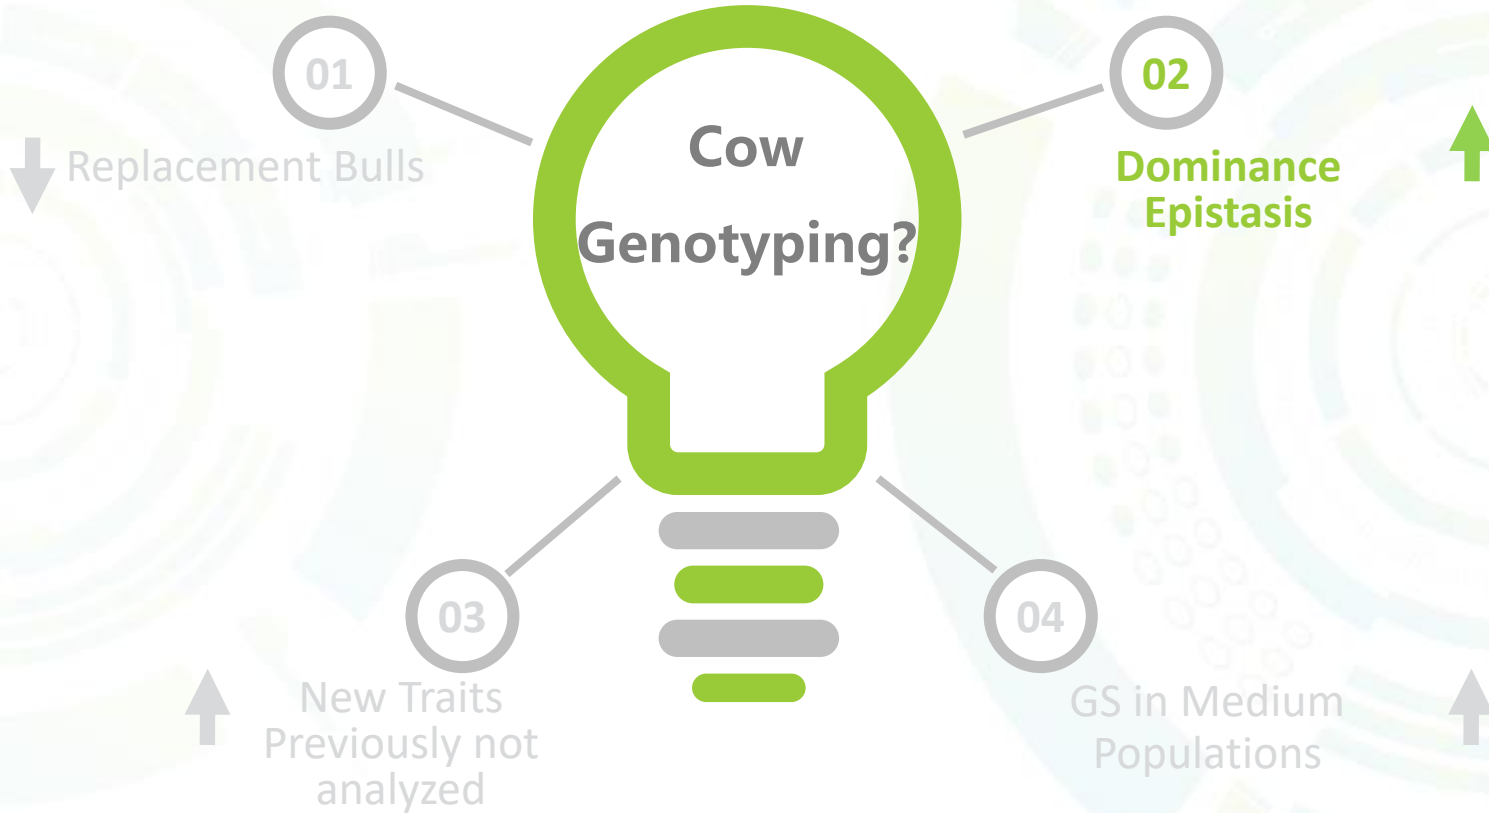

- **Non-additive genetic variance (NAGV) is usually omitted in Genomic Selection (GS) and when estimating life-time merit of cows**
- **GS is based on additive effects of sire**
- **Especially the case when reference population is made of progeny tested bulls**
- **But cows with own performances are becoming more popular as a resource of choice for GS**
- **If NAGV is substantial, it can ameliorate the life-time merit of cows if considered in addition to additive variation**

The promise

Data

Breeds

Phenotypes

Yield Deviation: Milk, Protein, Fat

11,000

20,000

46,000

10,000

12,000

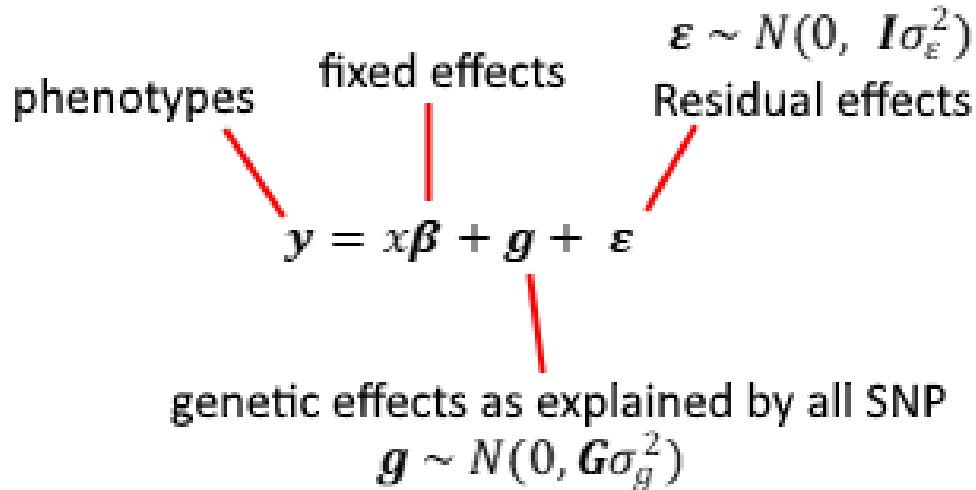

Genotypes

- Genotyped with 50k SNP chip
- 6,132 SNPs selected from whole genome sequence
- All imputed to 50k density

Selection of SNP with Major Effect

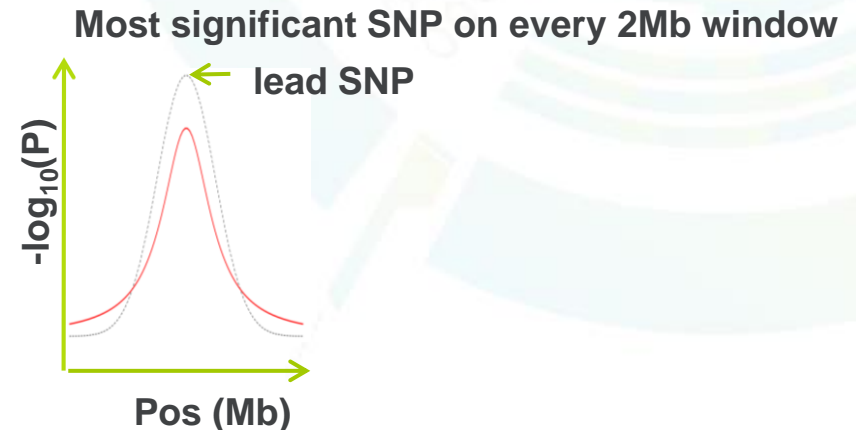

GWAS

$$\text{var}(\mathbf{y}) = G\sigma_g^2 + I\sigma_\varepsilon^2$$

- 539 SNP with major Effect

Non-additive models

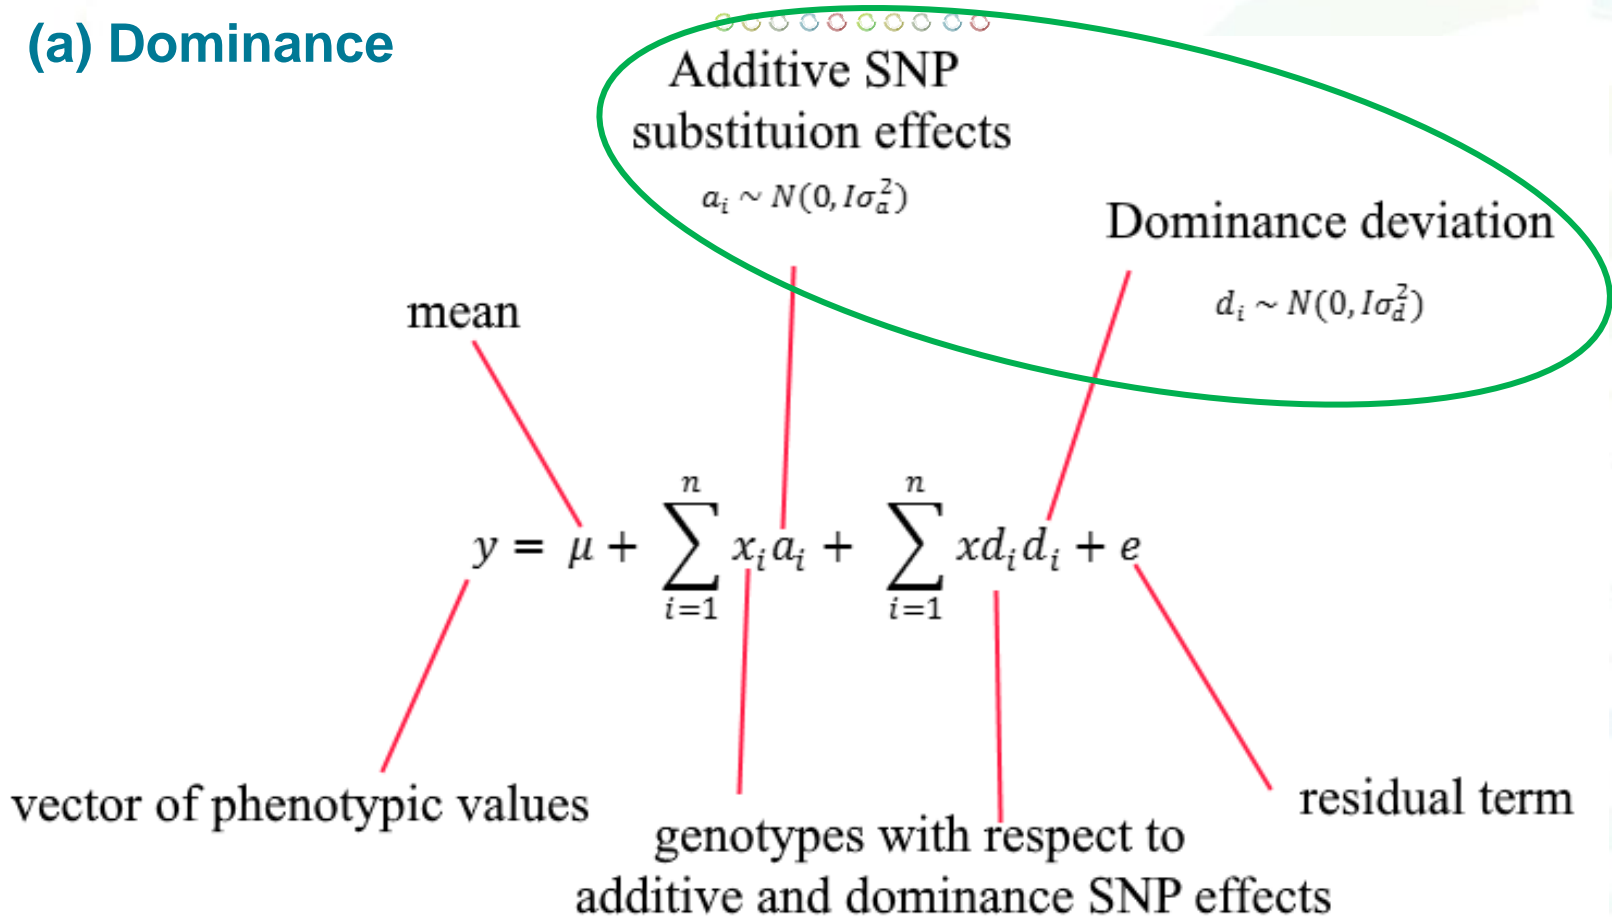

- **Symmetric marker coding**

W_{ij}	Locus k		
Locus j	AA	AB	BB
AA	1	0	-1
AB	0	0	0
BB	-1	0	1

Non-additive models

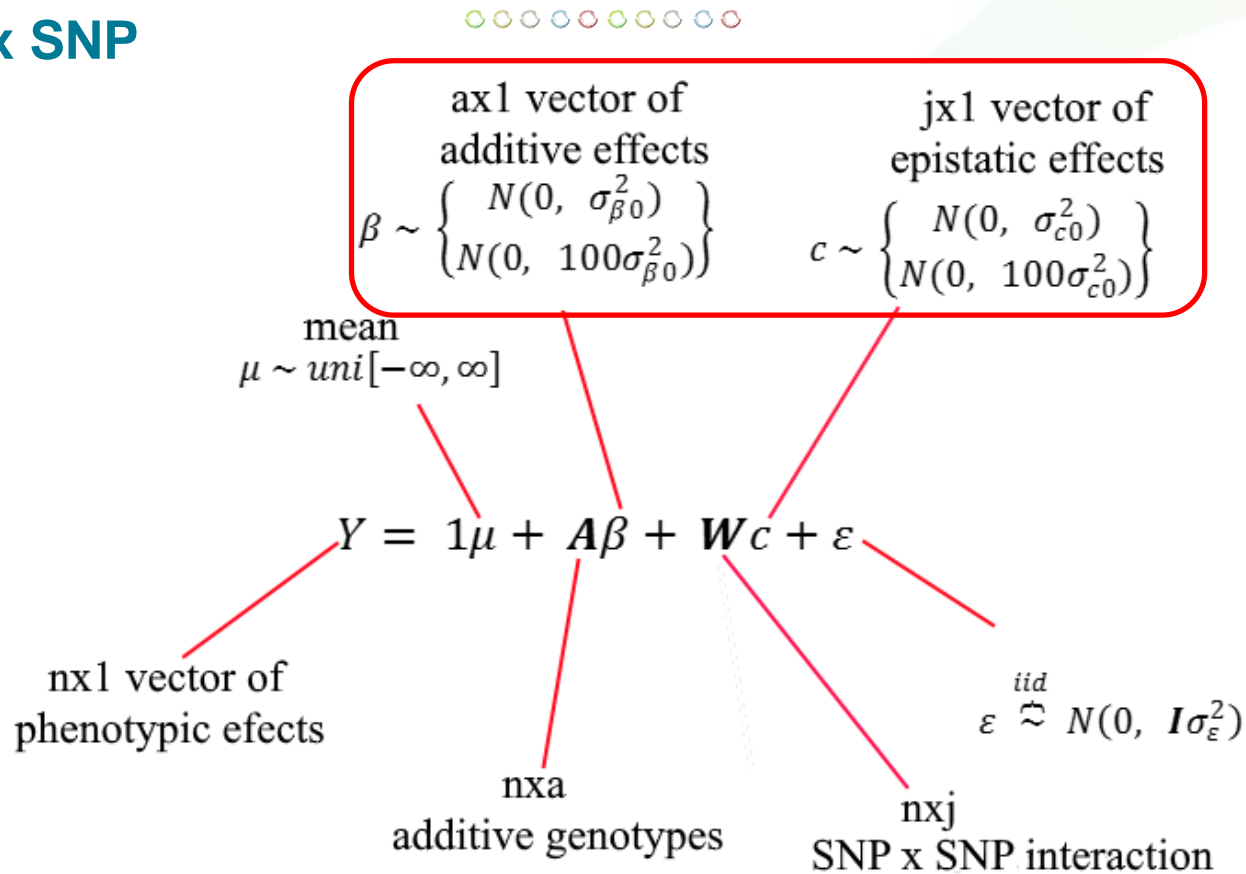

(a) Dominance

- Chain=200k, burn=50k, skip=0.5k
- Metropolis-Hastings sampler – (a)

Non-additive models

(b) SNP x SNP

$$(\pi\beta_0, \pi 100\beta_0) \sim beta(10,1) \text{ and } (\pi c_0, \pi 100c_0) \sim beta(10,1)$$

$$\sigma_{\beta_0}^2, \sigma_{c_0}^2, \sigma_{\varepsilon_0}^2 \sim uni[0, \infty]$$

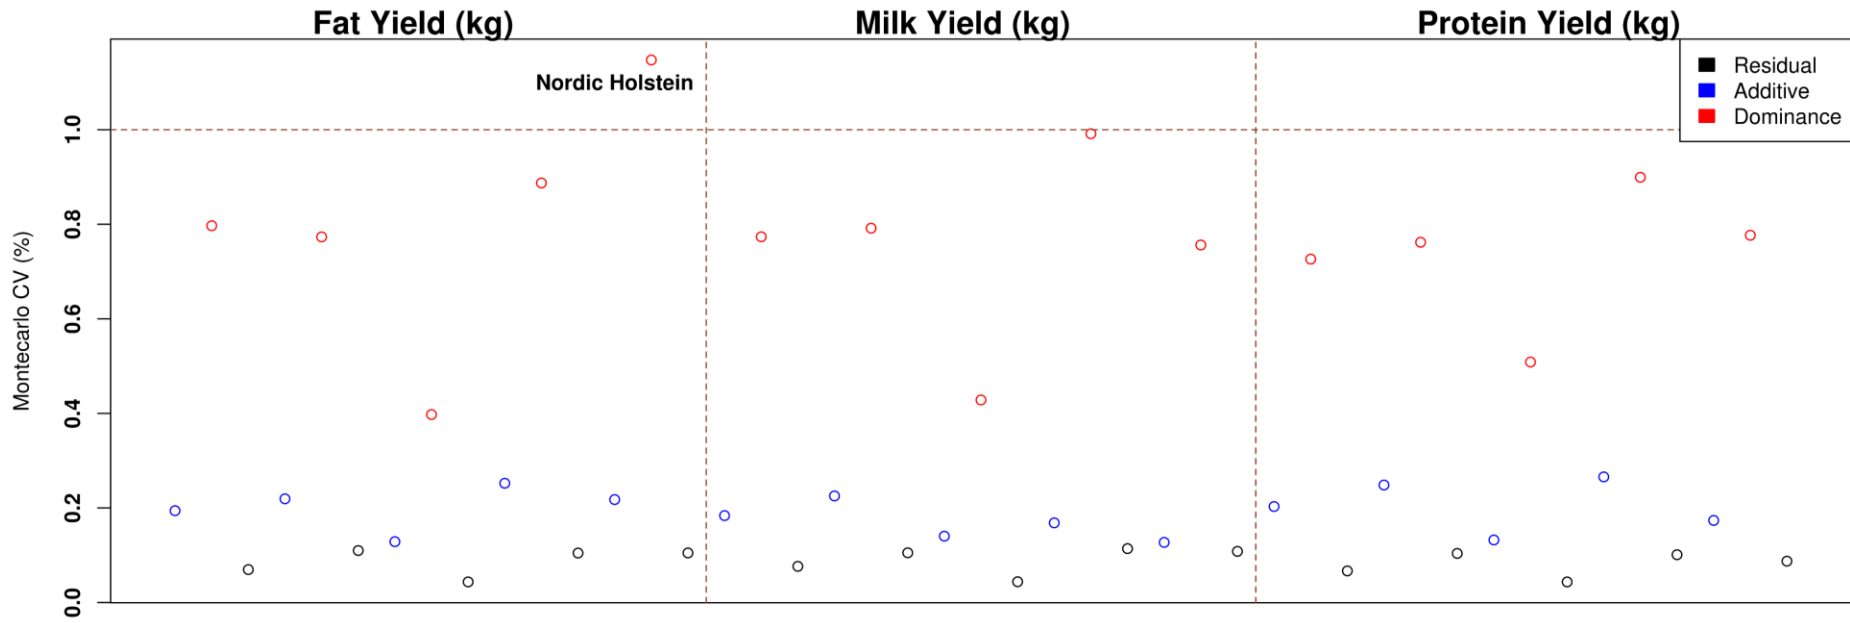

- Chain=200k, burn=50k, skip=0.5k
- Bernoulli distribution

Model Convergence

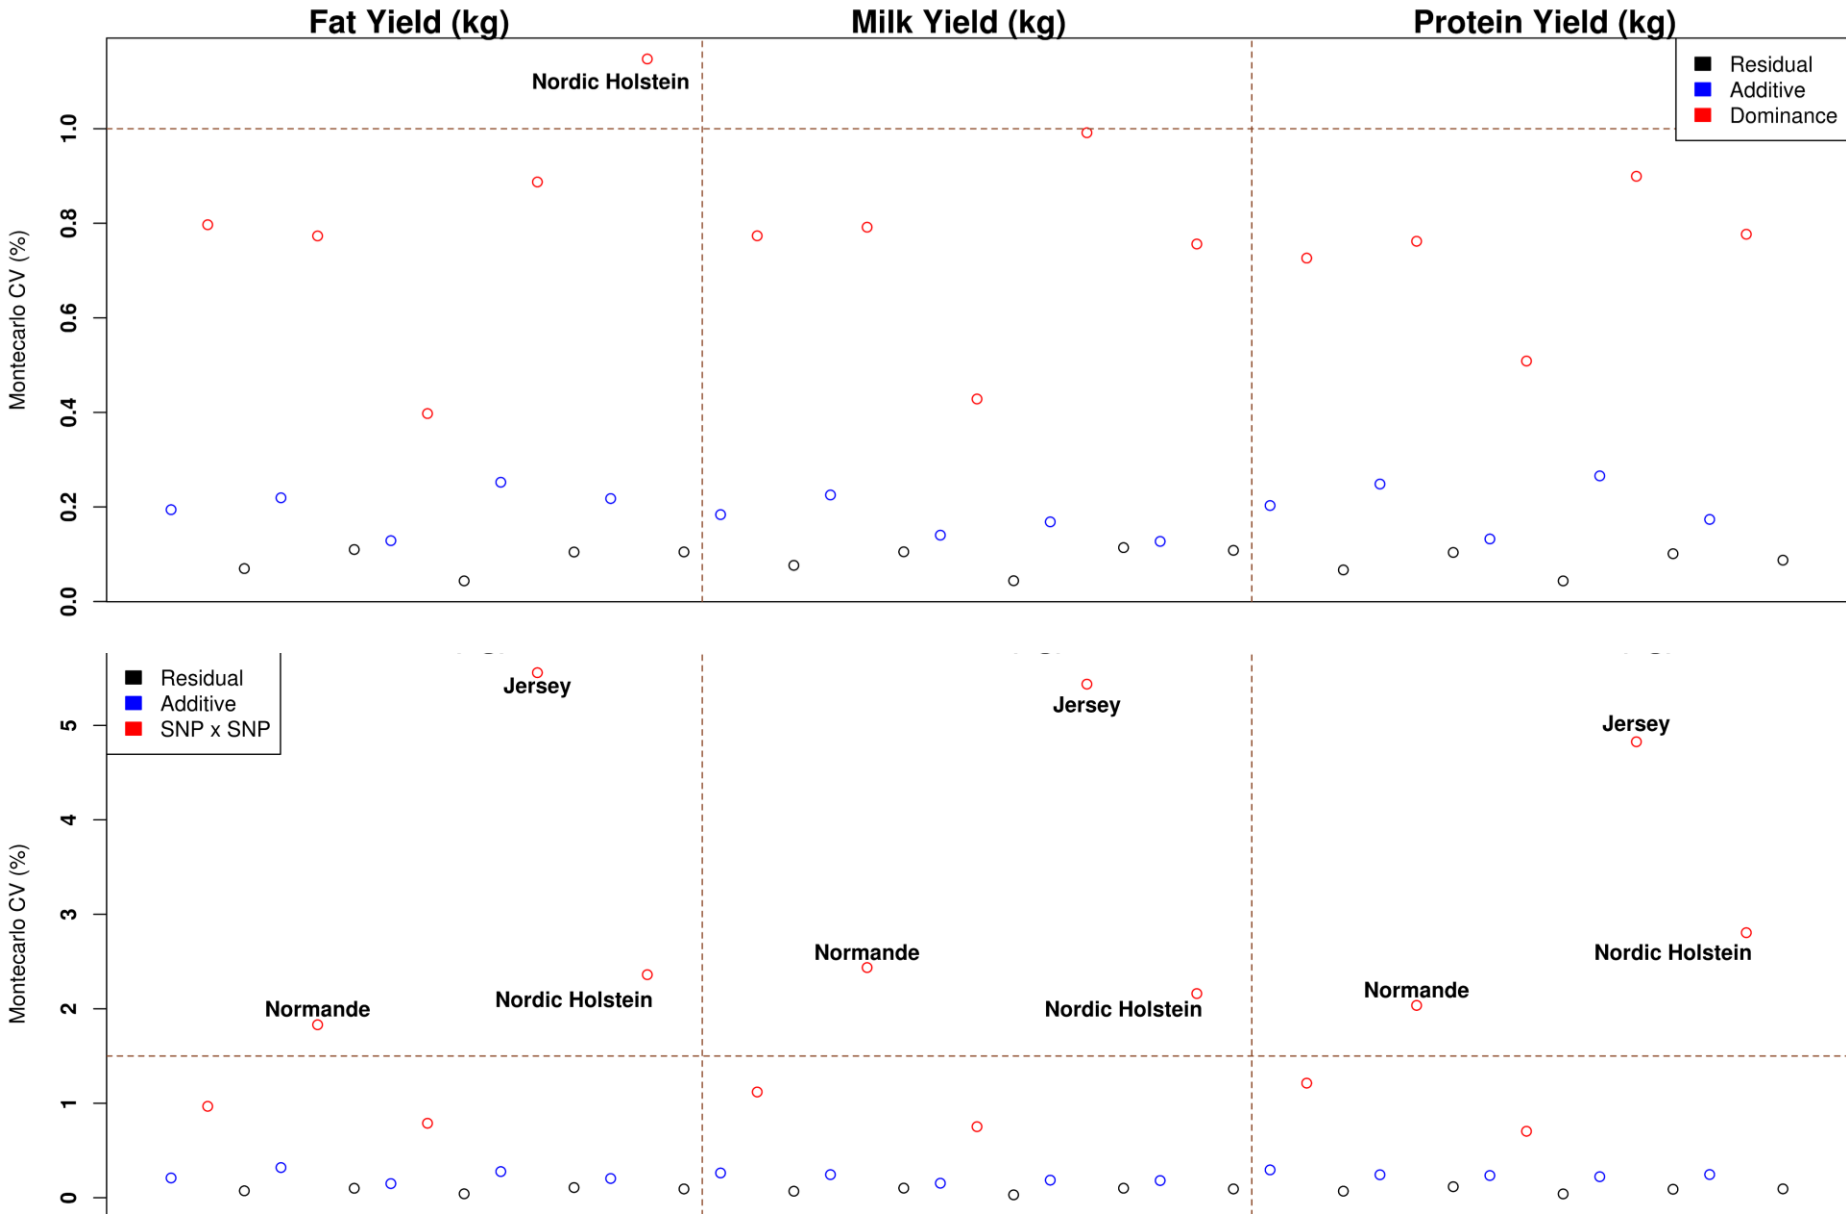

$$\text{MonteCarlo Coefficient of variation} = \frac{\text{Time Series SE}}{\text{Parameter Mean}}$$

Model Convergence

$$\text{MonteCarlo Coefficient of variation} = \frac{\text{Time Series SE}}{\text{Parameter Mean}}$$

Model Convergence

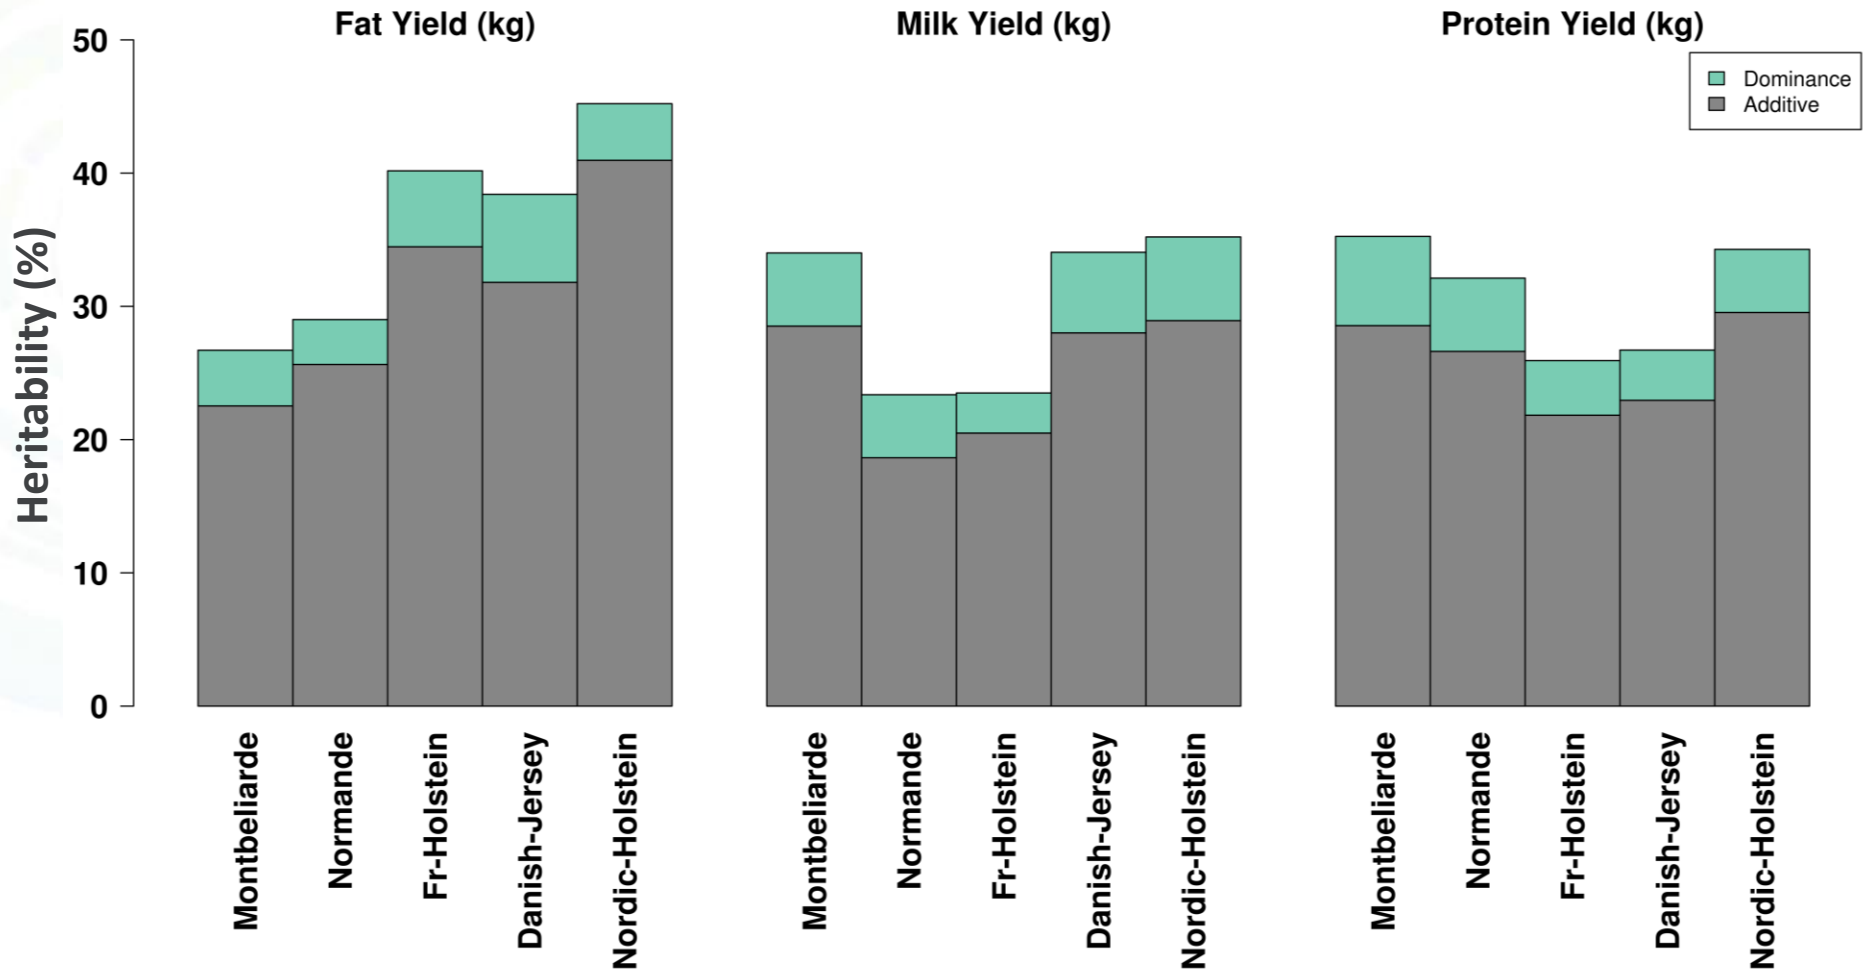

Heritability

variation in a trait due to variation in genetic factors as explained by SNP

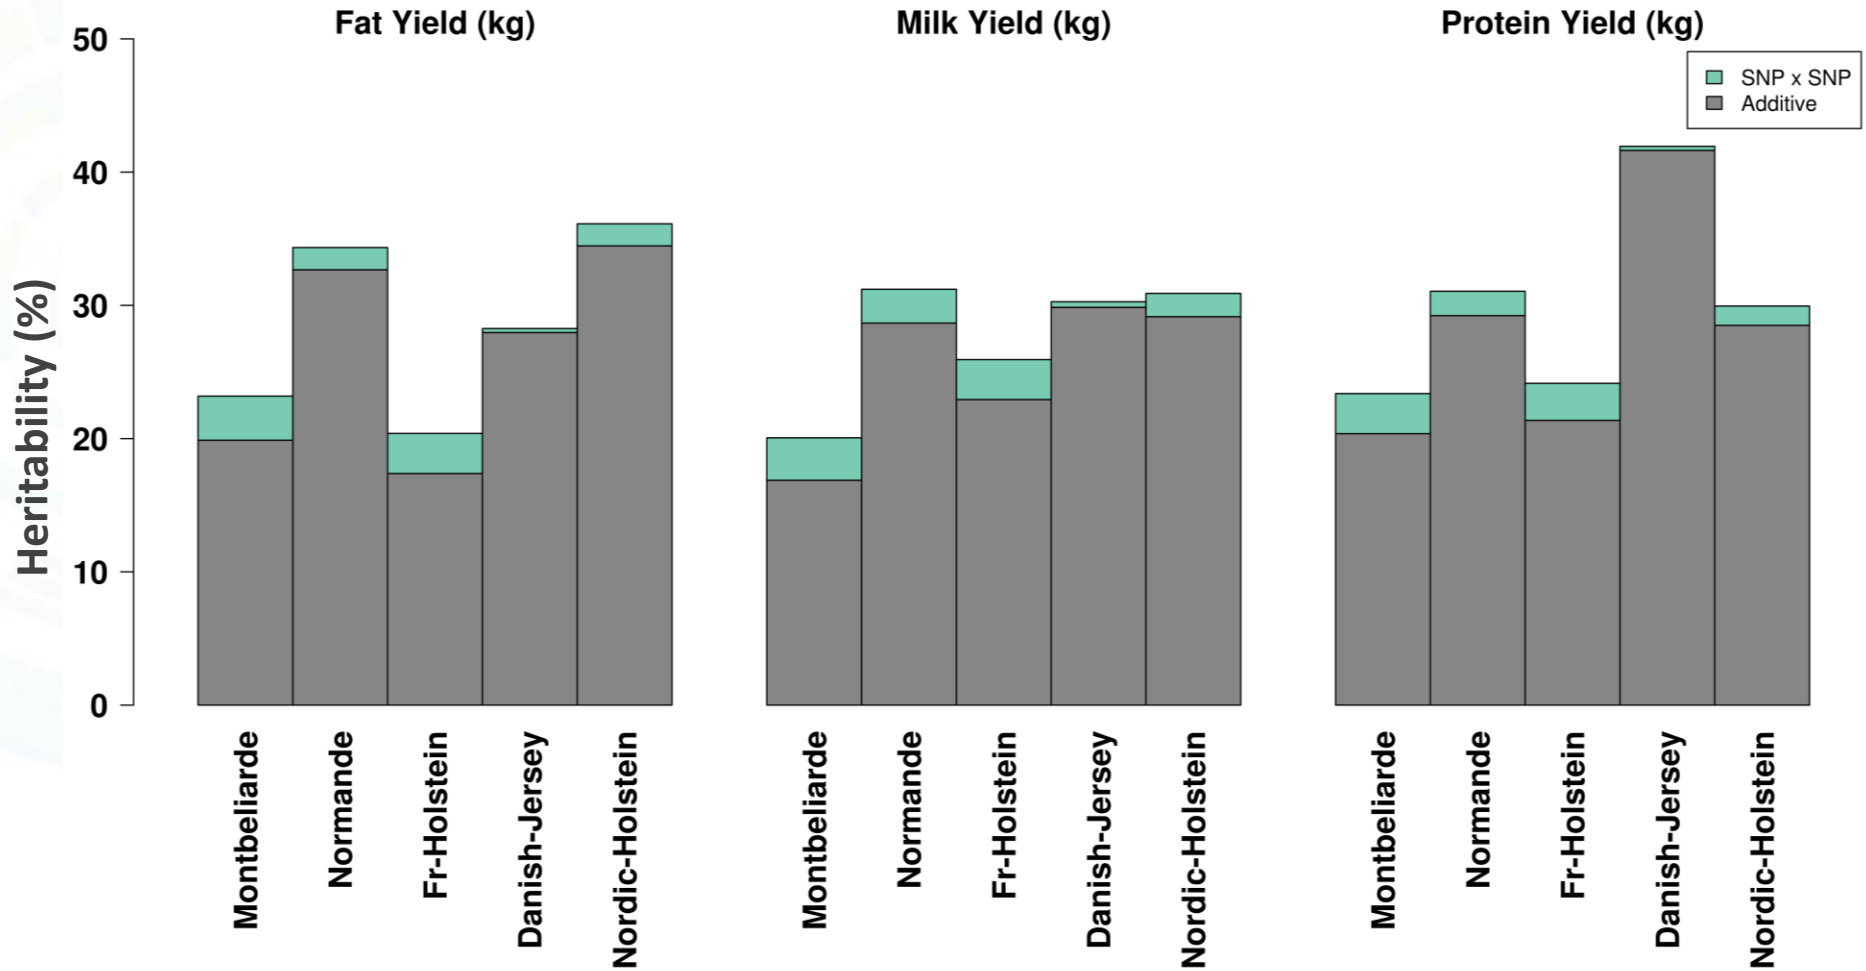

Dominance

Heritability

SNP x SNP

Allele Substitution Effect

SNP x SNP effects

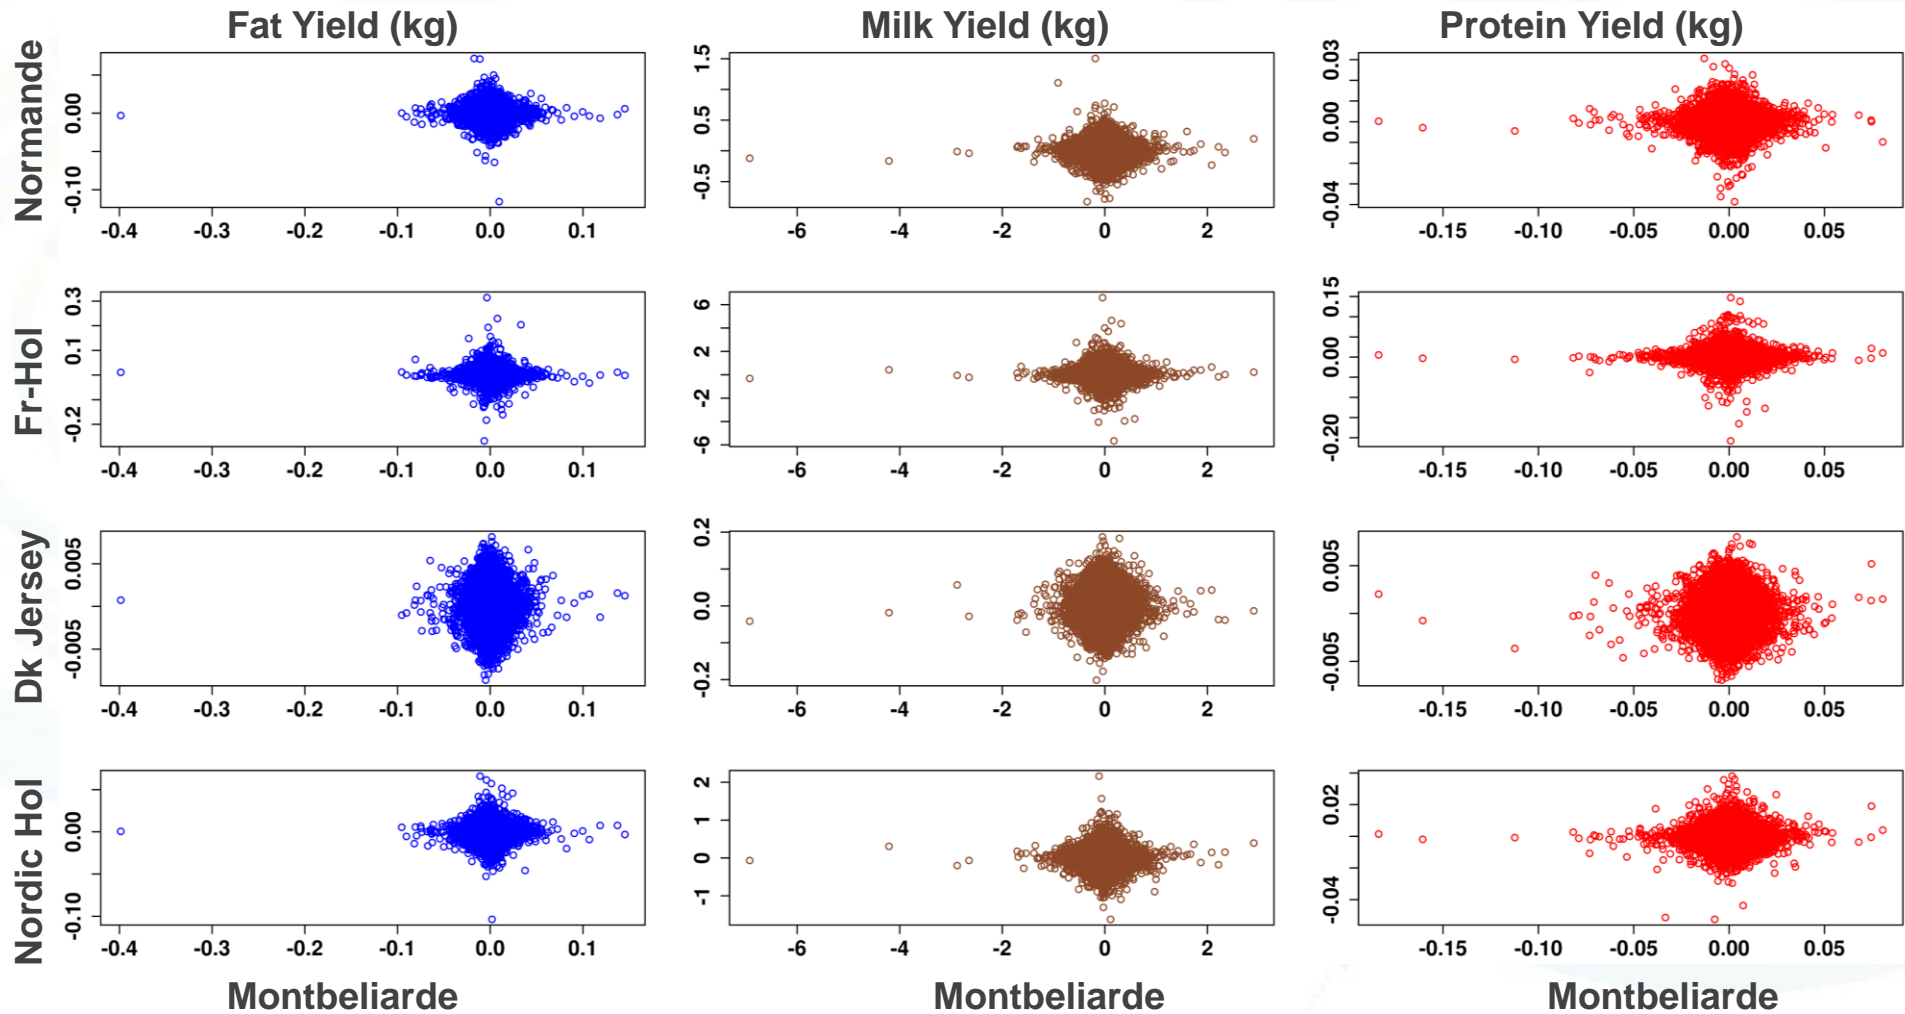

1. Across breeds same trait
2. Within breed different traits

Allele Substitution Effect

SNP x SNP effects

1. Across breeds same trait

Allele Substitution Effect

SNP x SNP effects

2. Within breed different traits

Conclusion

SNP with major effect including those selected from whole genome sequence explain non-additive variation

This interaction matrix can augment the normal GRM when predicting breeding accuracies
